

Bevel tutorial

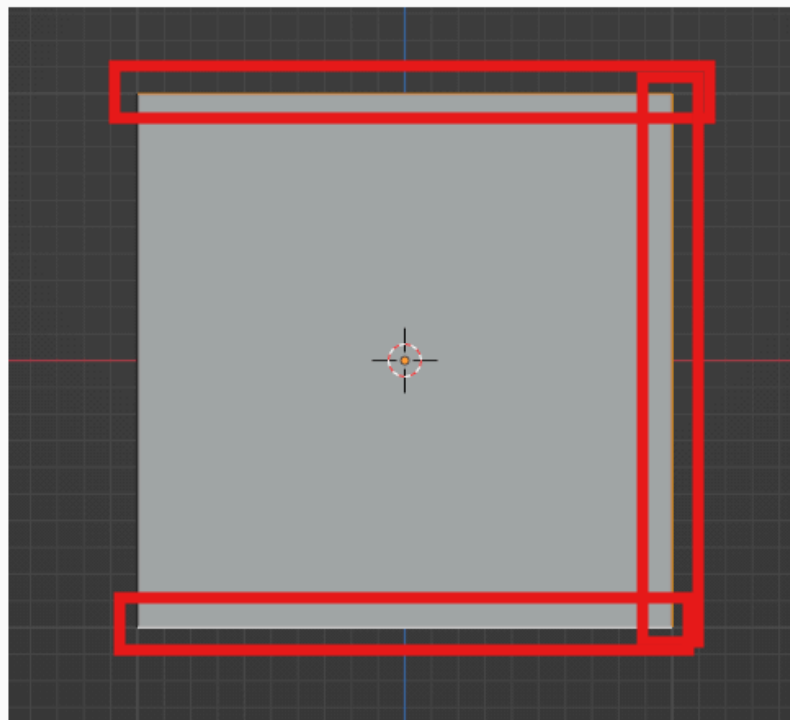

Important concepts covered: bevel

This tutorial is focused around the bevel operation.

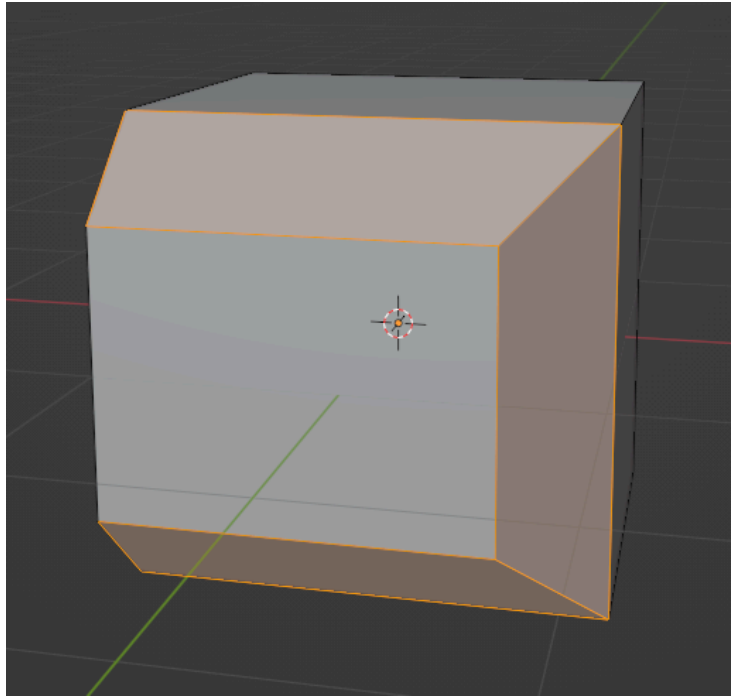

First, let's start by entering Edit mode and changing to Edge selection mode:

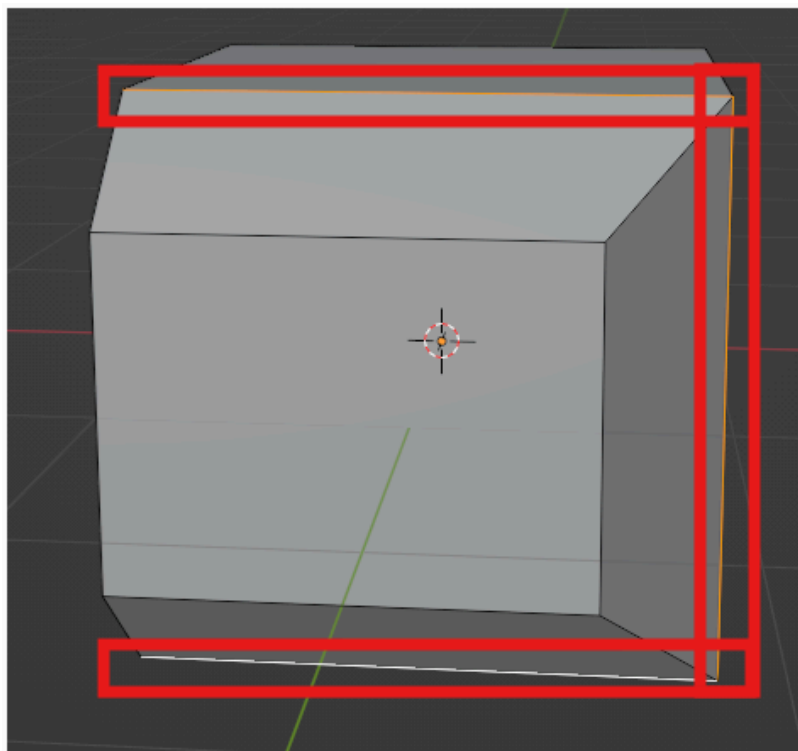

Go to the front view by pressing (NUMPAD 1) and select the following 3 edges:

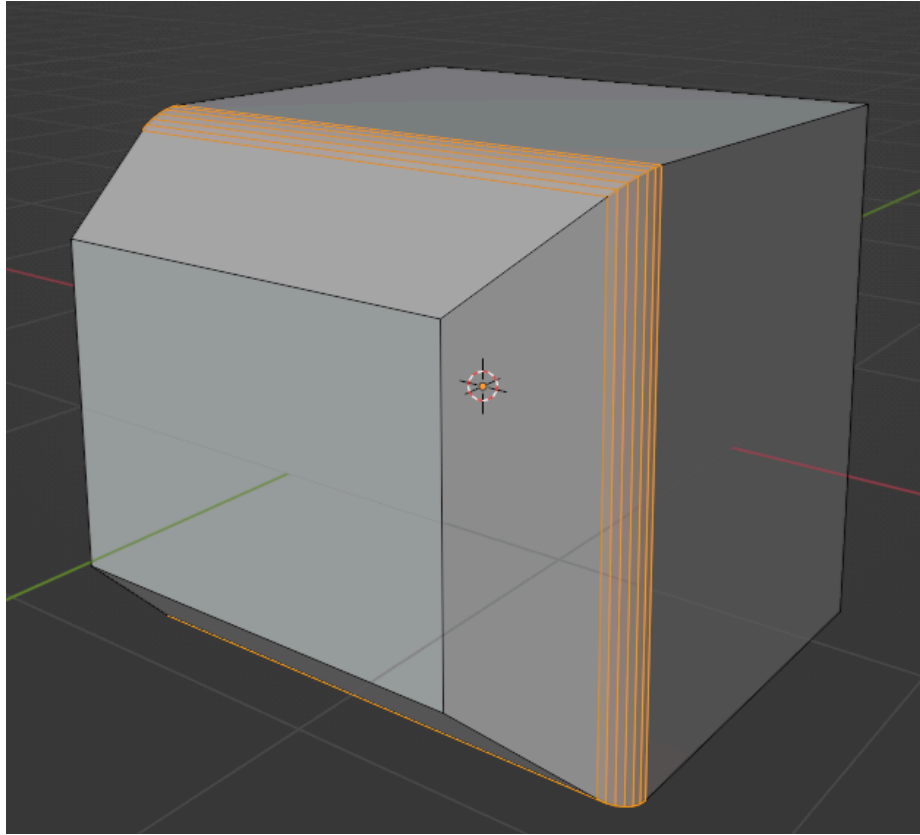

Then, press CTRL+B to bevel the edges and then type 0.4:

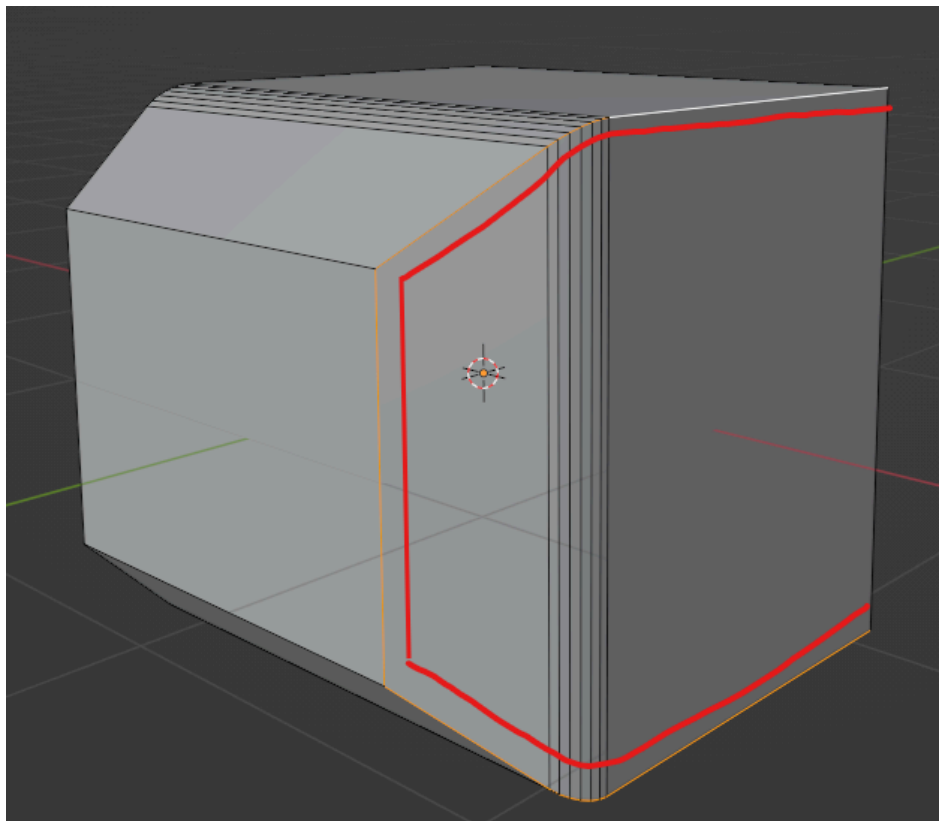

This is the bevel without any subdivision. But we can also add subdivisions to it. For example, select the following edges:

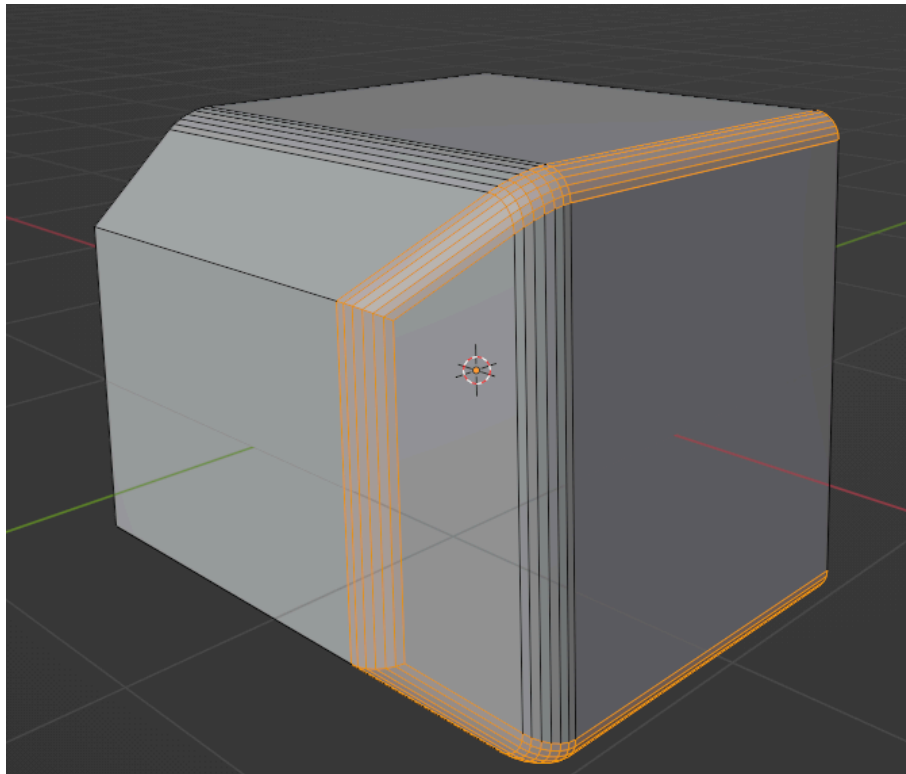

Bevel then by pressing CTRL+B again, type 0.1 and now, by using your mouse scroll, you can increase the number of segments added. On the bottom part of the screen, you can check how many segments you are adding. Add 6 segments:

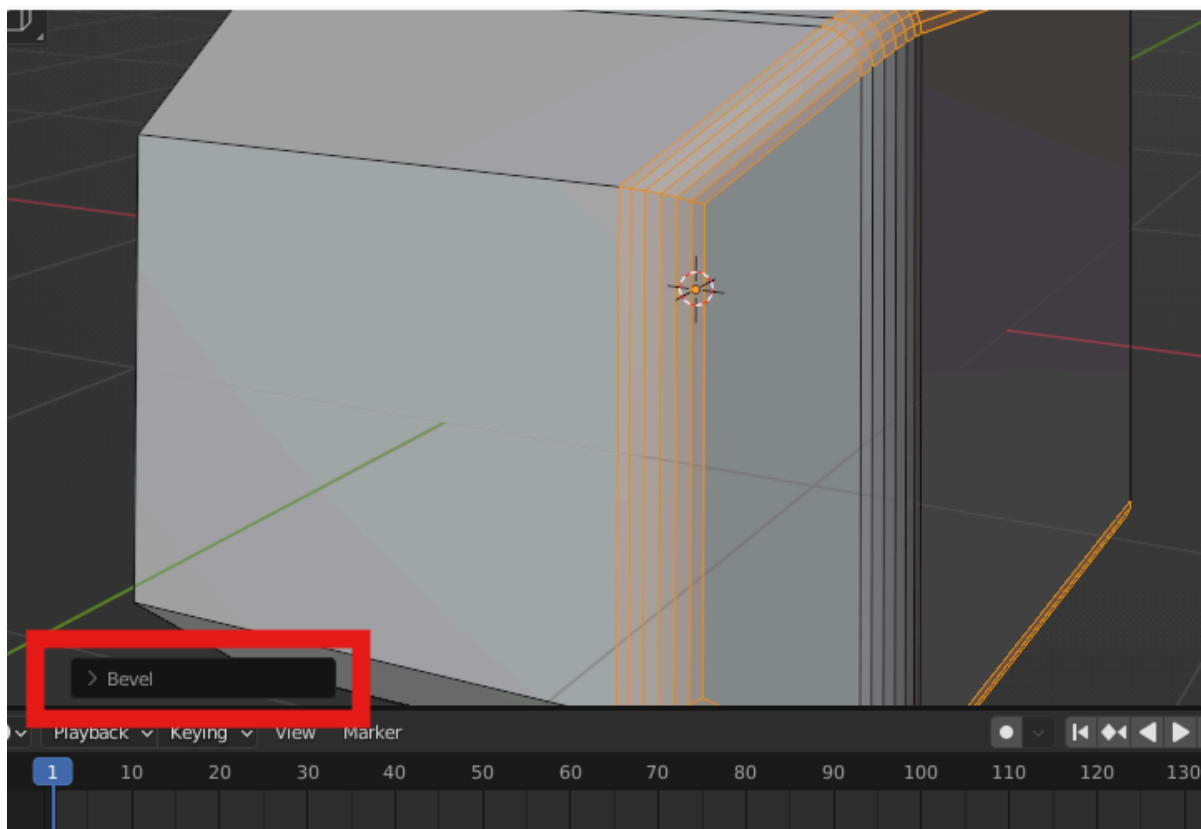

You can also change the profile of the bevel. To do this, let's select the following edges:

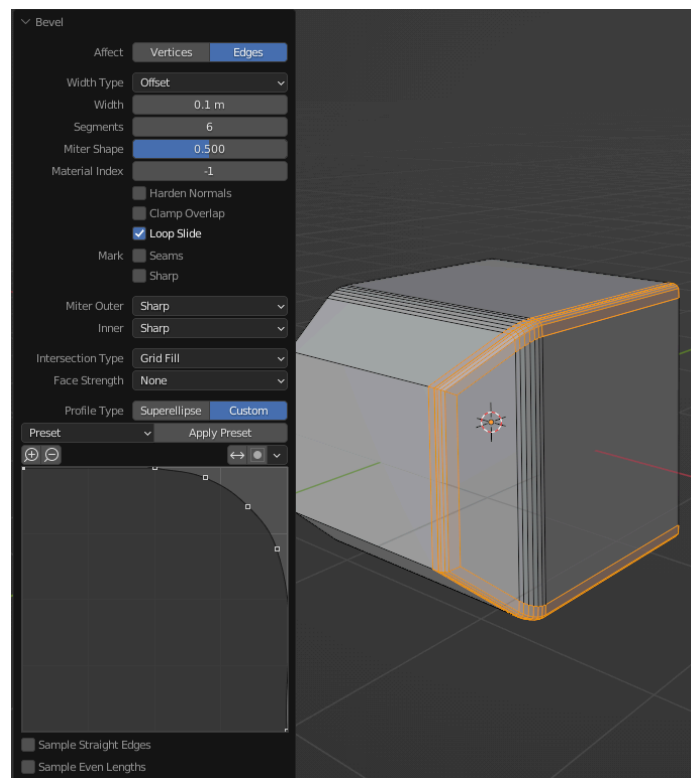

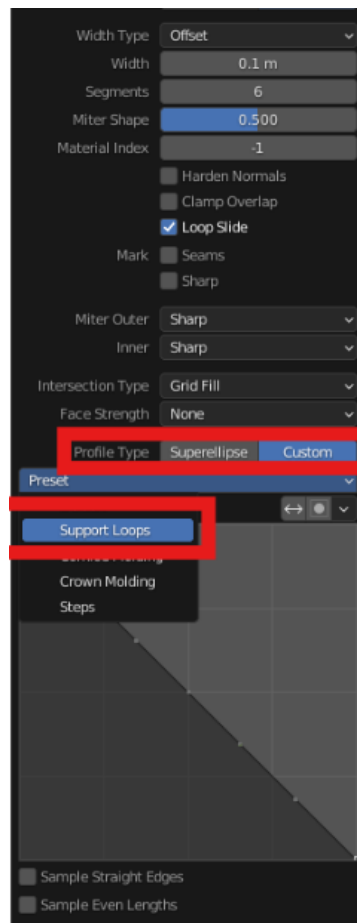

Now bevel again (CTRL+B), type 0.1 and keep the 6 segments as before:

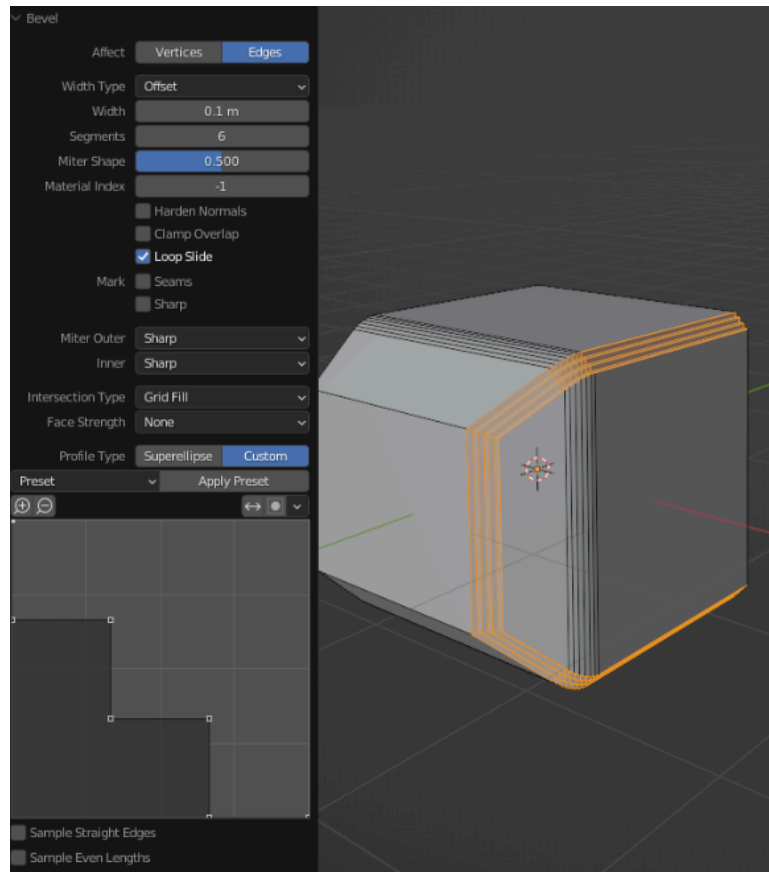

Now, you can see a dialog box has been created at the bottom left corner of the screen with the name “Bevel”. If you expand it you can see all the parameters set for the bevel operation:

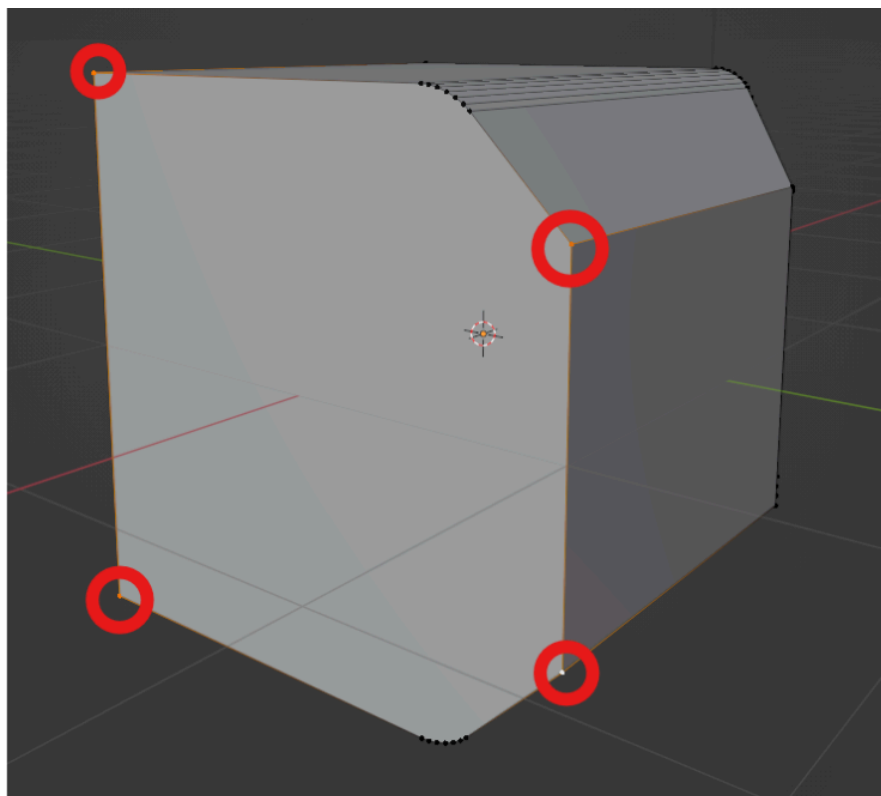

The last option is called “Profile Type”. If you change it to “Custom”, you will be able to change the format of the bevel. Click on “Preset” and choose “Support Loops” and see how it affects the profile:

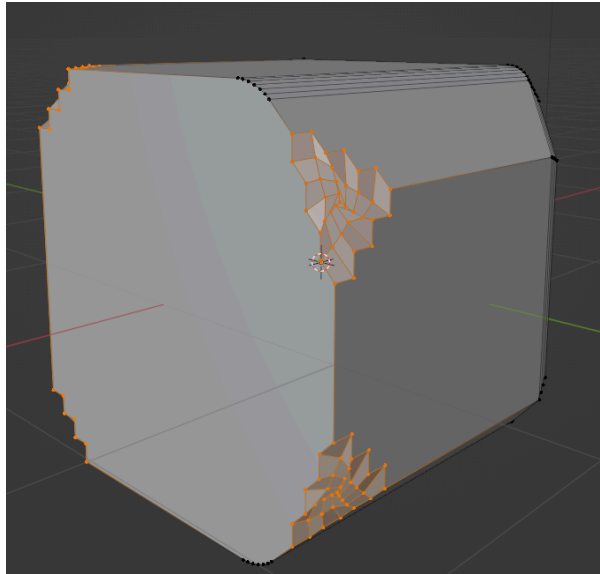

Now click again on top of “Preset” and choose “Steps”:

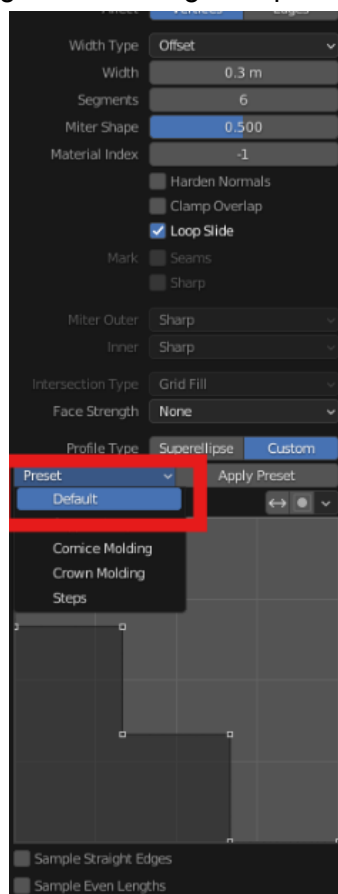

Now let's learn how to bevel vertices. To do so, change to vertex selection mode and select the following vertices:

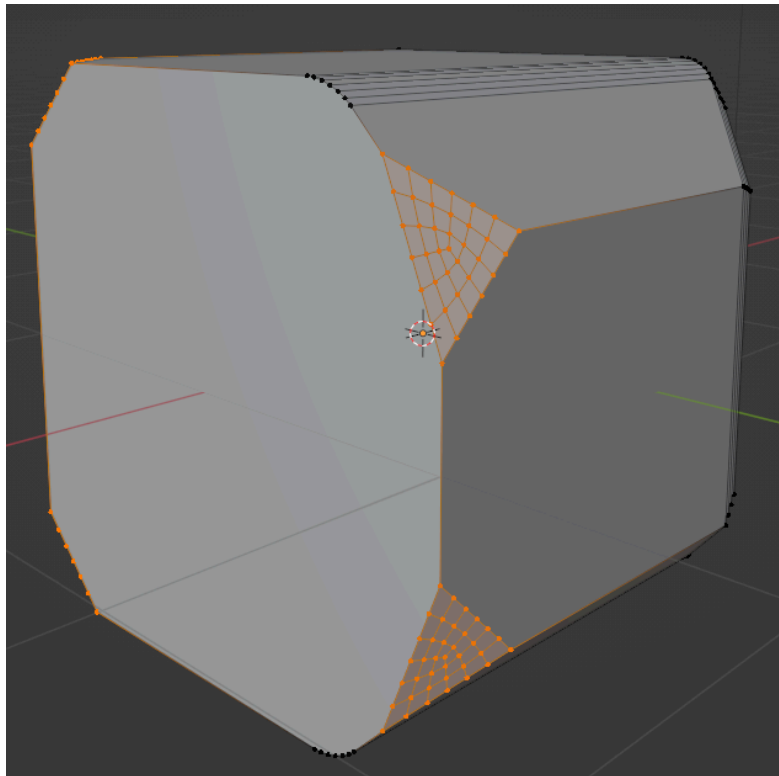

Press CTRL+B again to bevel and right after press “V”. This will enable you to bevel vertices. Then type 0.3 and confirm. You will have this:

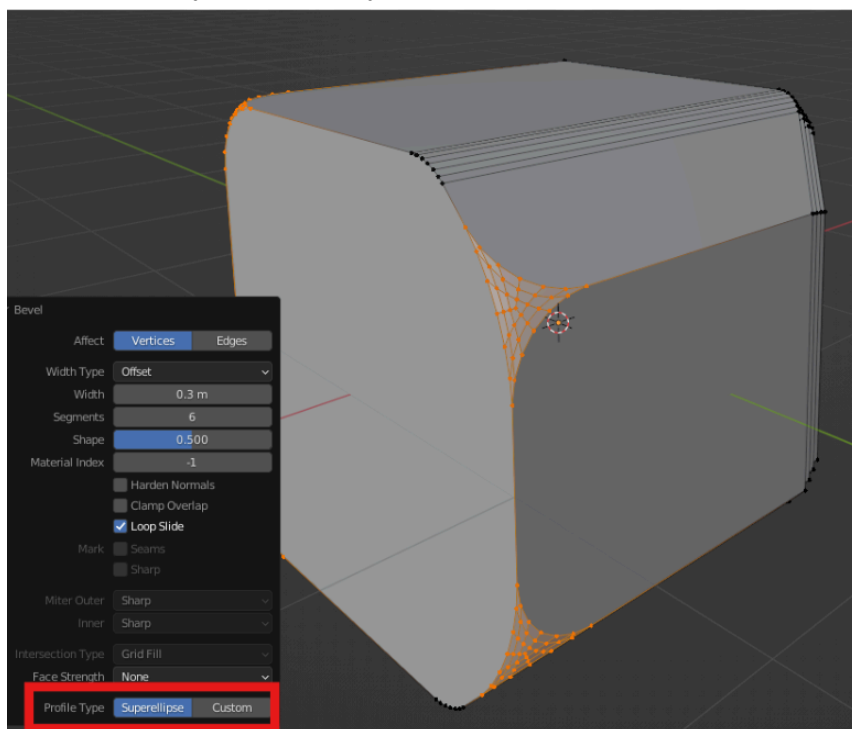

As you can see the mesh looks weird because it is trying to apply the step preset chosen before. So open the dialog box again and change the preset to “Default”:

As you can see the default is just a linear profile. To change it to round again, select “Superellipse” as a Profile Type and now you should have this:

This concludes the bevel tutorial.
